**Abstract.** This research article systematizes the current state and future perspectives of digital platforms in transport research, driven by increasing digitalization and data availability. Following an interdisciplinary expert workshop and a desk review of 36 non-commercial platforms, the study identifies EU regulatory frameworks (e.g., the ITS Directive) and viable commercial business models as primary drivers for data provision. The findings reveal a fragmented landscape where public and private mobility data availability is improving, yet significant deficits persist for specific research-generated data like travel surveys and field observations. The authors classify platforms by content and functionality, noting that most lack advanced analytical tools. The study concludes that establishing dedicated, secure platforms for research data, addressing privacy concerns and standardization is essential to maximize public funding impact and foster synergies between academia, urban planning, and private innovation.

## 1 1 The importance of digital platforms in transport research

2 Mobility and transport revolve around the movement of people, goods and data. Thanks to  
3 digitalization, the boundaries between these three types of movement are becoming increasingly  
4 fluid. Firstly, physical movement is increasingly being replaced by digital alternatives. For  
5 example, people who work from home no longer commute to the office, but instead generate data  
6 streams. Goods can be purchased in shops or can be ordered to be sent home, with either people  
7 or goods traveling. Secondly, digitalization also means that an increasing amount of data are  
8 available from travelers, public authorities, mobility service providers, vehicle manufacturers,  
9 and other stakeholders, including for example mobile phone companies. These new data sources  
10 and communication methods are enabling the development of innovative user-driven and demand-  
11 responsive Mobility-as-a-Service (MaaS) concepts that are tailored to individual users' needs,  
12 while offering viable business models. These new data sources also enable the continuous

13 monitoring of transport systems, with a better coverage of all system elements in terms of supply  
14 and demand, with a higher level of detail and timeliness, thereby supporting evidence-based  
15 strategic planning and policy-making. Finally, digitalization enables a shift in which transport  
16 users are no longer mere “passive particles” moving around in given transport systems that  
17 are taken for granted, but instead become active designers of these systems. Travelers request  
18 services, provide trip data and feedback on their travel experiences, and make suggestions for  
19 improving and tailoring the systems to their individual needs.

20 All these three developments arising from digitalization in transport come with great opportunities  
21 for research and planning practice. At the heart of these opportunities are digital platforms that  
22 provide all relevant stakeholders with information and data, as well as physical and digital  
23 mobility services. We define the term “digital platforms” for this study based on Steinberg (2022)  
24 [1] with two main variants:

- 25 • The layered stack model refers to a platform “as something upon which one stands” [1], this  
26 might be for example computer hardware, software, websites or social media. The platform  
27 is considered here as a “building block upon which organizations build complementary  
28 products or technologies”. [1]
- 29 • The horizontal intermediary model considers a platform to be a „mediatory device enabling  
30 third party transactions to take place”. Credit cards or the Uber app are examples of this  
31 concept. [1]

32 Both types of digital platform are currently experiencing significant changes and growth. At the  
33 European level, the ITS directive (Intelligent Transportation Systems) [2] and the supplementing  
34 Delegated Regulations ([3],[4][5],[6],[7] ) have formulated obligations to make data available  
35 to third parties and thus facilitate data exchange. National Access Points (NAPs) have been  
36 established in the EU Member States to implement this European legal framework, initially  
37 with a focus on road transport (truck parking [3], Safety-Related Traffic Information (SRTI) [4],  
38 and Real-Time Traffic Information (RTTI) [5], [7]. Other modes of transport are increasingly  
39 also considered (see e.g., the Multi-Modal Traffic Information Services, MMTIS), resulting in a  
40 substantial increase of institutions that now are requested to make their data publicly available.  
41 The Federal Highway and Transport Research Institute (BAST) has been established as the NAP  
42 in Germany. The “[Mobilithek](#)” will be the platform used for data provision, in collaboration with  
43 the emerging [Mobility Data Space](#), which is a virtual marketplace for the exchange of sensitive  
44 mobility data.

45 This means that public institutions engage in defining the legal framework for digital platforms,  
46 thereby ensuring that these platforms contribute to societal goals.[1] In addition, public institutions  
47 increasingly engage in the development of digital platforms for providing the own data, and  
48 also data from private companies. Private companies are investing in the development of digital  
49 platforms because they recognize the potential for profitable business models in the provision of  
50 data and mobility services.

51 Transport research will benefit significantly from the improved data availability, new research  
52 questions will emerge around innovative user-driven mobility services, and entirely new fields  
53 of research can be expected around the platforms themselves, including, for example, profitable

54 business models for platform operation or the regulatory framework. At the same time, transport  
55 research will increasingly be required to make its own data and research results available to  
56 others. This needs digital platforms for hosting and providing the often sensitive data generated  
57 in transport research. The landscape of existing digital platforms relevant to transport research is  
58 fragmented, and to the best of our knowledge, there is no systematic overview. However, such  
59 an overview and systematization would be necessary to capitalize on the opportunities arising  
60 from the three digitalization trends presented above, to decide which platforms are suitable for  
61 providing data from transport research projects, and, where appropriate, to contribute to the  
62 strategic further development of existing platforms or the development of new ones.

63 This study was designed to address these gaps. It aims to examine and systematize the current  
64 state and future prospects of digital platforms relevant to transport research, and to explore  
65 related research opportunities. This systematization should cover all relevant aspects, including  
66 data types, stakeholders and platforms. We are interested in both aspects of (1) data and services  
67 provided at current and possible future digital platforms, and (2) platforms that might host data  
68 collected in the own transport research projects.

69 To achieve these goals, we first organized an expert workshop with an interdisciplinary audience  
70 of researchers who are using data and services from digital platforms for their own research,  
71 and/or who conduct research on digital platforms themselves. The goals of this workshop were  
72 to compile an overview of current and possible future digital platforms, identify opportunities  
73 and risks related to these platforms for transport research and planning practice, and to exchange  
74 ideas on related research opportunities. Second, we conducted a desk research on existing digital  
75 platforms with relevance for transport research, this desk research is called environment analysis  
76 in this article.

77 This article presents the concepts and main results from the workshop and the environment  
78 analysis, followed by a synthesis and an outlook for further research and recommendations  
79 for shaping the future landscape of digital platforms with relevance for transport research and  
80 planning practice in order to maximize their benefits for research and planning practice.

## 81 **2 Workshop “Digital platforms for transformative urban mobility”**

### 82 **2.1 Concept**

83 The workshop “Digital Platforms for Transformative Urban Mobility” was held at TU Dresden,  
84 “Friedrich List” Faculty of Transport and Traffic Sciences on 27-28 April 2023. The following  
85 key questions were formulated for this workshop:

- 86 • What digital platforms are currently in place in the transport sector, and what platforms  
87 should be in place in the future, in order to facilitate innovative research and to maximize  
88 the benefits of digitalization for travelers, mobility service providers, public authorities  
89 and society as a whole?
- 90 • Which institutions and stakeholders should operate the platforms?
- 91 • What are the appropriate legal and economic frameworks to enable private engagement  
92 and economic success of digital platforms while contributing to societal ambitions, such

- 93 as the Sustainable Development Goals (SDGs) adopted by the United Nations [8]?
- 94 • How are digital platforms transforming human labor, mobility, and habitats?
- 95 • To what extent do digital platforms increase precarity and/or prosperity?
- 96 • How to design digital platforms and governance schemes that can successfully engage
- 97 travelers to contribute to these platforms with data, activities, suggestions, etc., and thus
- 98 ultimately participate in the design of future transport systems?
- 99 Interdisciplinary researchers working on digital platforms in general, and more specifically on
- 100 digital platforms in mobility and transport were the main target audience for this workshop.
- 101 Potential participants were actively screened and approached with personalized invitations,
- 102 resulting in a group of 22 early to advanced career researchers from six countries and a range
- 103 of disciplines, including transport, humanities, social sciences, economics, political science,
- 104 data science, law and urban planning. The group was complemented by a legal expert and a
- 105 representative of the German Federal Highway and Transport Research Institute (BAST), so that
- 106 the perspective of the German National Access Point (NAP) according to the EU ITS (Intelligent
- 107 Transportation Systems) Directive was also present.
- 108 The program was designed as a combination of keynote speeches by renowned researchers,
- 109 presentations by participants and interactive group work. In the two interactive sessions, partici-
- 110 pants were divided into two respectively three groups. The first session focused on the current
- 111 situation, while the second session invited participants to look ahead and formulate expectations
- 112 and requirements for future platforms. Similar questions were used for both group work sessions:
- 113 Stakeholders:
- 114 • Which stakeholders engage today / will engage in the future in setting up platforms for
- 115 data and services in mobility and transport?
- 116 • What interest do / will they have?
- 117 • Which platforms do / will they operate?
- 118 • Which types of data, services do / should they provide?
- 119 • Which relevance do / should these platforms have for research and for practice?
- 120 Platforms:
- 121 • Which platforms for mobility data exist today / should exist in the future?
- 122 • What kind of data and services do they provide / should they provide?
- 123 • Who runs / should run these platforms? With what motivation?
- 124 • What relevance do / will these platforms have for whom?
- 125 Data and services:
- 126 • What types of data and services exist / will exist in mobility and transport (items to be
- 127 provided on platforms) and how is this data provided / how should this data be provided
- 128 by whom?

129 Challenges and opportunities:

- 130 • What are the challenges and opportunities for current / future digital platforms in the
- 131 context of mobility and transport?

132 Research perspectives: What research needs do you see? What ideas do you have to address

133 these research needs?

134 Participants were invited to discuss the questions and document the discussion with cards on

135 pinboards, grouped into: stakeholders, platforms, data and services, challenges and opportunities,

136 and research perspectives. The expected outcomes of the interactive sessions were pinboards with

137 cards grouped into the categories introduced above (see 5.2 ). In the second session, high priority

138 was given to developing ideas for future platforms, including features such as functionalities and

139 governance schemes, and to noting related research ideas.

## 140 2.2 Summary of keynote speeches and participants' presentations

141 Four keynote speeches by renowned researchers offered interdisciplinary perspectives, gave

142 inspiration and broadened the horizons of all participants.

143 Prof. Charlotte Halpern from Science Po, Centre for European Studies and Comparative Politics

144 (Paris, France), spoke about “Data as a critical resource for governing sustainable urban mobility”.

145 Drawing on her background in political science and her own previous research (see e.g. [9]),

146 she outlined current governance arrangements in urban and transport planning and provided

147 future perspectives. Resources for implementing policy measures and capacity building for local

148 stakeholders, including data literacy, are key to evidence-based planning, which is a prerequisite

149 for achieving societal goals. The emergence of new data sources and platforms offers promising

150 opportunities for innovative governance schemes and evidence-based planning. However, the

151 public administrations and also policy makers, particularly in smaller and less affluent cities,

152 are not yet well prepared to make use of these opportunities. Future research could support

153 the development of frameworks that incentivize digital platforms and the provision of data to

154 support societal goals, rather than focusing solely on the success of individual companies.

155 Prof. Marc Steinberg from Concordia University (Montreal, Canada) spoke about the “Automobile

156 Lineages of the Platform Economy”, based on his critical research on the various forms of

157 platforms and their effects on the economy, society and political discourse (see e.g. [1]). He

158 introduced layered stack models and horizontal intermediary models as the two main variants

159 of the platform concept, and identified parallels and interdependencies between automobile

160 production and platform capitalism. Both are based on the concept of platforms as layered

161 stacked models and horizontal intermediary models, both use the term platform, both place a high

162 priority on just-in-time and lean delivery of their products and services, both are data-driven and

163 outsource risks to external partners such as suppliers or Uber drivers. The relationship between

164 platforms and organizational practices was also highlighted.

165 Prof. Orit Halpern works in the fields of history and cybernetics, bridging the history of science,

166 computing, and cybernetics with design. In her keynote “Models and Cities: Re-imagining

167 Smartness”, she outlined key concepts related to platforms and the smartness mandate.[10]

168 Platforms should not be reduced to devices that serve specific purposes (e.g., smart phones, cars,

169 homes, cities) but rather be seen as ways of managing life with serious implications for society,  
170 politics and the environment.[10]

171 Prof. Travis Waller's background is in transport network modeling, based on innovative methods,  
172 data, and ethics-based metrics for evaluating the different possible solutions. In his keynote  
173 speech "Moving Into the Future: Infrastructure as Platform and Mobility as a Resource",  
174 Prof. Waller introduced the novel concept of Mobility as a Resource (MaaR), based on the  
175 hypothesis that mobility has moved from a product (e.g., vehicles) to MaaS, and is now evolving  
176 towards a resource (MaaR). The MaaR concept envisions a future where mobility and infras-  
177 tructure can be commoditized and flexibly allocated to different uses, and thus managed as a  
178 resource. Prof. Waller outlined key characteristics of the MaaR concept, possible applications  
179 and research needs in the fields of transport network management, demand behavior, mixed  
180 mode use, and equitable mobility. [11]

181 Overall, the four keynote speeches with their interdisciplinary perspectives, novel ideas and open  
182 questions, provided great inspiration for the subsequent workshop discussions.

183 The participants' presentations were grouped into three main themes: (1) MaaS concepts, (2) reg-  
184 ulatory frameworks, and (3) innovative data and platforms. Most presentations focused on the  
185 first theme. Participants shared their perspectives on MaaS as a concept in which different pas-  
186 senger transport services are brought together through an online platform that includes services  
187 such as trip planning, payment, ticketing and real-time information for all the different services.  
188 Key characteristics of MaaS include a focus on customer needs, bundling of services, cooperation  
189 and interconnectivity of transport modes and service providers.[12] Examples of MaaS services,  
190 their impact on travel behavior and system-wide effects were presented ([13],[14],[15],[16]). The  
191 goal of sustainable mobility was used as a normative framework in most presentations, leading  
192 to the question of how MaaS platforms need to be designed to contribute to progress towards the  
193 sustainability goal.[16] The importance of appropriate institutional frameworks and governance  
194 arrangements was also highlighted.[17]

195 Presentations in theme (2) provided an overview of the current legal frameworks and future  
196 perspectives, with a focus on the ITS directive (Intelligent Transportation Systems) [2] and the  
197 supplementing Delegated Regulations ([3],[4],[5],[6],[7]). Innovative data and platforms were  
198 presented in theme (3). The VAMOS-lab at TU Dresden (Verkehrsanalyse-, Management- und  
199 Optimierungssystem / traffic analysis, management and optimization system) was established in  
200 2003 and has since developed into an innovative and powerful tool for monitoring and controlling  
201 road traffic in the city and region of Dresden. Approximately 1,800 sensors feed their data into  
202 the VAMOS lab, measuring vehicle volume, speed, traffic quality (Level of Service) and parking  
203 activities. The vision for the VAMOS lab is to establish a premier data platform that provides  
204 high-quality processed traffic data as a basis for innovative research and educational activities.  
205 Open geodata infrastructures and digital planning tools to support mobility transitions were also  
206 presented, and ways to incentivize the provision of data necessary for the successful operation of  
207 any platform were discussed.

## 208 2.3 Results

209 Workshop results can be grouped into (1) stakeholder groups and roles, (2) groups of digital  
210 platforms, (3) data types and sources in transport research, (4) challenges and opportunities in  
211 operating digital platforms in transport, and (5) perspectives for future research.

212 **(1) Stakeholder groups and roles:** The following seven main interest groups are to be considered  
213 according to the workshop participants:

- 214 • Travelers mainly want to reach their destinations comfortably, safely, flexibly, reliably and  
215 at low cost. They use data and services from digital platforms and possibly also contribute  
216 to digital platforms, e.g., with data or service requests.
- 217 • Public authorities provide transport systems and services. They need to make sure that all  
218 person groups reach their destinations, and they need to minimize negative effects from  
219 transport (e.g., noise, air pollutants, greenhouse gases).
- 220 • Public authorities also provide the legal framework (legislature) for the development and  
221 operation of digital platforms and the use of data, which should support societal goals.
- 222 • Public transport companies are mainly private companies, but still obliged to offer services  
223 for all person groups and parts of the city. Like commercial companies, they have to think  
224 in business terms while also serving the public interest.
- 225 • Commercial companies include operators of mobility services, providers of navigation  
226 services and IT infrastructure, and industry. These companies seek to maximise their  
227 revenues, which can be generated through the provision of platforms, data and/or services.
- 228 • Political decision-makers need data and services from digital platforms as the basis for  
229 evidence-based decision-making in the management and further development of transport  
230 systems.
- 231 • Researchers benefit from data provided at the digital platforms for their own research, and  
232 collect data themselves, which should be made available.

233 Most stakeholder groups can take on several roles. Table 1 provides a summary of the identified  
234 stakeholder groups and their roles in the context of digital platforms in mobility and transport.

**Table 1:** Stakeholder groups and their roles

Stakeholder group	Operate platforms	Provide data	Provide services	Use data	Use services	Set legal framework
(Potential) travelers	(x)	x		x	x	
Public authorities	x	x	x	x	x	
Public transport operators	x	x	x	x	x	
Operators shared mobility services	x	x	x	x	x	
Operators ridesourcing, ridepooling	x	x	x	x	x	
Commercial companies						
Providers navigation services	x	x	x	x	x	
Providers IT infrastructure	x					
Industry	x	x	x	x	x	
Legislature						x
Policymakers				x	x	x
Researchers	(x)	x	x	x	x	

"x" current and possible future roles, "(x)" only possible future roles

235 **(2) Groups of digital platforms:** Table 2 provides an overview of the identified groups of  
236 digital platforms with relevance for transport research. Platforms are mainly operated by public  
237 institutions or private companies, interesting business cases exist already today and new business  
238 cases can be expected in the future. Only one platform providing research data was named by

239 participants, this is the VAMOS platform run by the Chair of Traffic Process Automation at TU  
240 Dresden.

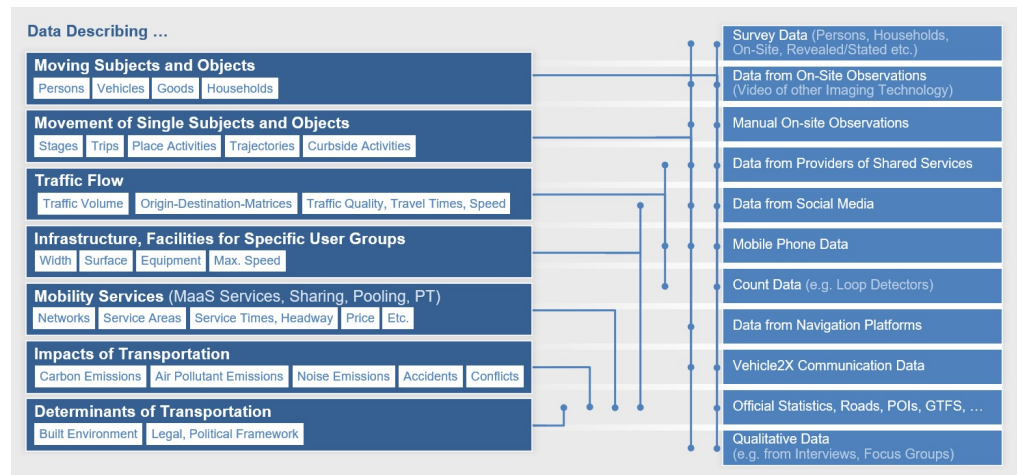

**Table 2:** Groups of digital platforms with relevance for transport research, provided data and services

Groups of digital platforms	Provided data and services
Open data portals cities, digital twins	All types of data owned by local public authorities (e.g., Dresden, Berlin), digital twins mainly include built environment data (e.g., Helsinki, Transport for London)
Platforms providing research data	Various data types, e.g., traffic counts/traffic speed/occupancy of parking garages in VAMOS
Platforms with crowd sourced data	Infrastructure data, Points of Interest (POIs), e.g., OpenStreetMap, Mapillary
Commercial platforms providing map data	HERE, Google Maps, Microsoft Bing, Apple Maps, etc.
Commercial platforms providing navigation services	Moovit, Google, DB Navigator, smartphone apps by local stakeholders, etc.
Commercial platforms providing mobility services, including passenger and commercial transport	Public transport services (lines, departure times, ticketing etc.), on-demand services (ridepooling, ridehailing etc.), shared services (cars, bicycles, scooters)
Commercial platforms providing data on users and uses of transport systems	Floating Car Data (FCD) (e.g., TomTom), Floating Bicycle Data (FBD) (e.g., from the City Cycling-Campaigns in Germany, from sports platforms such as Strava)
NAPs, Mobility Data Space	Mainly public data according to the ITS Directive
Social Media Platforms	Communication and location data (e.g., Instagram, Bluesky, Mastodon, LinkedIn)

241 **(3) Data types and sources in transport research:** Figure 1 provides an overview of the types  
242 and sources of data identified in the workshop discussion and subsequently systematized by  
243 the authors for this paper, including data that are already provided or should be provided in  
244 the future. For transport demand, data types describe the moving subjects and objects, their  
245 movements from origins to destinations, and the resulting traffic flow, such as the traffic volume  
246 of a particular mode of transport on a particular road section. For transport supply, data types  
247 describe infrastructure and services. Data describing the determinants and effects of transport  
248 activities are also relevant. The many sources of data relevant to transport demand and supply are  
249 shown on the right-hand side of Figure 1. A wealth of data is available for transport systems, and  
250 data availability can be expected to further improve in the coming years thanks to digitalization  
251 trends.

252 **(4) Challenges and opportunities in operating digital platforms in transport:** Several chal-  
253 lenges and opportunities were named by the workshop participants. By far the greatest importance  
254 was assigned to (1) privacy issues and (2) the relevance of data.

255 1. Privacy issues: The establishment and continued adoption of the legal framework on  
256 privacy issues is therefore of utmost importance, as stressed by all participants. A balance  
257 needs to be struck between ensuring privacy and allowing platforms to operate and data

**Figure 1:** Data types and data sources in mobility and transport

258 to be exchanged. Variation in the temporal and spatial level of detail of the data was  
 259 mentioned as one way of achieving this balance; the establishment of data trustee centers  
 260 could be useful to make data available at a more detailed scale. Overall, data should be  
 261 available as openly as possible, with access restricted where necessary. This is a key  
 262 prerequisite for trust in data and services; trust is needed to motivate stakeholders to use  
 263 data and services and to contribute their own data.

264 2. Relevance of data: Platforms, data and mobility services are not ends in themselves. Rather  
 265 they should support societal goals and be relevant. Tech4Good was mentioned several  
 266 times, and a societal discourse is needed to define what the meaning of "good" is in this  
 267 context. A common vision should be developed as the basis for all political decisions on  
 268 which digital platforms should be established, who should operate them, and on how they  
 269 should be regulated legally to optimally support societal goals. The focus should always  
 270 be on the user and on providing the best possible mobility services and transport systems.

271 **(5) Perspectives for future research:** The following themes were discussed in terms of perspec-  
 272 tives for future research:

- 273 • Standardization should receive more attention to improve compatibility of data formats,  
 274 interfaces etc. Collaboration with the various initiatives in research data management (e.g.,  
 275 NFDI) might help to make progress in this field.
- 276 • Test beds, living labs, open urbanism – such collaborative formats can be supported by  
 277 digital platforms and higher availability of mobility data. Innovative governance systems  
 278 and participatory planning processes can support the scaling up of such experiments and  
 279 data-driven, evidence-based planning.
- 280 • Challenges and opportunities are interlinked; only interdisciplinary research can address  
 281 them comprehensively; current silos in government and policy-making need to be broken  
 282 down to take advantage of the opportunities associated with the emerging digital platforms.
- 283 • Data literacy in research and practice needs increasing attention in the education of future  
 284 transport professionals and also in filling open positions in the different relevant institutions.

- 285 • The high relevance of quality management, especially for commercial data, was mentioned  
286 several times. Public authorities should provide support in identifying biases in data and in  
287 enforcing transparency and high quality also for data and services provided by commercial  
288 companies.
- 289 • The transition between the digital and the physical systems is fluent as demonstrated  
290 by Steinberg[1], meaning that interdependencies should be considered in research and  
291 practice.
- 292 • Increasing redundancy and overlap between data and services provided by different plat-  
293 forms can be expected in the future, particularly in fields with viable business cases.  
294 Such overlapping data offers the opportunity to analyze the same indicators (e.g., traffic  
295 volumes) based on different data sources and thus to search for systematic patterns in the  
296 similarities and differences between the different data sources.
- 297 • Research on incentive schemes for donating data and engaging in citizen science will be  
298 helpful to motivate relevant stakeholder groups efficiently.
- 299 • The importance of IT infrastructure providers will increase with more complex platforms  
300 with more functionalities, interactions, etc.

301 Overall, there was consensus that the opportunities associated with the emergence of digital  
302 platforms outweigh the risks. The increasing number of sensors (e.g. in vehicles and infrastruc-  
303 ture) and data sources opens up promising opportunities to improve the performance of transport  
304 systems in terms of safety, efficiency and other criteria according to the preferences of local  
305 stakeholders.

### 306 3 Environment analysis

#### 307 3.1 Approach

308 Participants' feedback from the workshop was complemented by a subsequent systematic desk  
309 review of non-commercial digital platforms with datasets relevant to mobility and transport to  
310 increase coverage and to ensure that relevant platforms are considered comprehensively. First, we  
311 searched the meta repositories Registry of Research Data Repositories ([re3data](#)), the NFDI4Ing  
312 [Data Collection Explorer](#) and the Zenodo Generalist Repository Comparison Chart [18] with the  
313 search terms "transport", "mobility" and "traffic". Second, we added platforms that we knew  
314 from our own expert network. Third, we added the platforms mentioned during the workshop to  
315 the list. In total, 36 platforms were identified with this combined approach. They were assessed  
316 based on the following grouped criteria[19]:

- 317 • organization and operation
- 318 • thematic focus and provided data types
- 319 • functionalities for data storage and provision
- 320 • support of the FAIR principles
- 321 • data access and

- 322 • user management
- 323 • options for statistical evaluation

### 324 **3.2 Results**

325 In addition to the comprehensive overview of the relevant information infrastructures, a key  
326 finding of the analysis is the identification of various approaches to characterize and classify the  
327 different platforms with relevance for mobility and transport:

#### 328 **Platforms providing data from public authorities**

329 These platforms exist at all levels, from the local to the international level, with a wide variety  
330 in the scope of the provided data. Open data portals are operated by multiple municipali-  
331 ties (e.g., Berlin, Dresden, London), states (in Germany “Bundesländer”) (e.g. Sachsen at  
332 <https://www.opendata.sachsen.de/>), national authorities such as the Federal Statistical Office of  
333 Germany (e.g., GENESIS) and at the European level (e.g. European Union Open Data Portal,  
334 INSPIRE Geoportal). The scope of the provided data corresponds to the responsibility of the  
335 institutions: It is broad for the municipal open data portals and the platforms from statistical  
336 offices, while the scope is narrower for specialized institutions such as the German Federal Motor  
337 Transport Authority with its focus on the road vehicle fleet in Germany. Specialized repositories  
338 with relevance for transport also exist, for example the German crash data map (Unfallatlas),  
339 maps showing traffic states (e.g., for Berlin at <https://viz.berlin.de/>) and data from automatic  
340 count stations (e.g., from the Federal Highway and Transport Research Institute BAST). Data  
341 from National Travel Surveys (NTS) (and other surveys addressing the two upper left-hand  
342 boxes in Figure 1) are provided via dedicated platforms in many countries. Data are usually  
343 provided upon request in a manual procedure to account for the high sensitivity of these data in  
344 terms of privacy. The Clearingstelle at DLR was responsible for this in Germany until the end of  
345 2024, when BAST took over this task.[20]

346 The higher-level platforms often aggregate data from lower-level repositories. For example, the  
347 Federal Geoportal in Germany (operated by the Federal Agency for Cartography and Geodesy,  
348 [geoportal.de](http://geoportal.de)) collects metadata from various sources, including municipal open data portals  
349 and specialized institutions. Similarly, the INSPIRE Geoportal of the European Commission  
350 aggregates metadata from national and regional repositories, providing a comprehensive overview  
351 of geospatial data across the EU, including transport-related data. While these higher-level  
352 platforms can address the issue of data fragmentation across various platforms, this often comes  
353 at the cost of specificity and discoverability of relevant data.

#### 354 **Platforms providing transport research data**

355 General repositories without any specific disciplinary focus are provided by individual institutions,  
356 and also at national and international levels. We identified only one open repository with a  
357 dedicated focus on transport research data, this is the [FID move repository](#). Besides, we have  
358 identified only very few platforms with a dedicated focus on research data from transport and they  
359 provide mainly data collected at a specific institution (e.g. ETH travel data archive (which seems  
360 not to be updated anymore), pedestrian dynamics data archive) or they have been established  
361 within EU-funded research projects and seem not to be updated after the projects have ended  
362 (e.g. TinnGO, SUITS). General repositories such as [GESIS](#) for social science data have also

363 been assessed and were found to provide very few datasets with relevance to transport research.

### 364 **Crowd-sourced data platforms leverage citizen-generated data**

365 Unlike traditional data sources, these platforms collect data voluntarily contributed by users  
 366 through digital channels, offering data that are often unavailable through official datasets. This  
 367 includes at least three types of platforms: (1) Collaborative mapping (e.g., OpenStreetMap)  
 368 provide user-generated data about infrastructure and the mobility space, often under free licenses.  
 369 (2) Social media provides a massive source of movements of people due to its deep user pen-  
 370 etration. (3) Specialized mobility platform applications continuously collect user-contributed  
 371 information about service usage, quality of service, and more. These applications often operate  
 372 in mixed forms (e.g., Moovit and Google Maps combine official as well as crowd-sourced data).

373 Furthermore, the analysis has shown that the portals can be classified according to the data they  
 allow to be uploaded and according to their subject-specific focus (see figure 2).

	Upload of own data possible	Only data from the platform or its sources
Cross-disciplinary content	4TU.ResearchData / figshare / Research Data Repository RADAR / Zenodo	BAW-Datenrepository / Bfa Statistik, CODE-DE / data.gouv.fr / darta.gov / data.gv.at / Data Portal Sydney / EU Open Data Portal / GENISIS-Online / GOVDATA / Open Data Berlin / OpenDataPortal Dresden / opendata.swiss / Statistikportal / TU Wien Research Data / UK Data Service
Transport and Mobility-specific content	FID move / mobilithek	Caltrans PeMS, Clearingstelle Verkehr, CMISST, ETH Travel Data Archive / FDZ Kraftfahrt-Bundesamt, MobilDataBW, Mobilität in Städten - SrV / Mobility Data-Campus / NHTS Data Center / Open Data BALM / Open Data ÖPNV / Pedestrian Dynamics Data Archive / SUITS Data Repository / TinnGO Open Data Repository

**Figure 2:** Overview and classification of the analyzed data platforms

374

375 We have also assessed the functionalities of the identified platforms, distinguishing between the  
 376 following four levels:

- 377 • Level 1: Long-term and stable data storage.
- 378 • Level 2: Level 1 + Robust rights management.
- 379 • Level 3: Level 1-2 + Advanced search functions and visualization tools.
- 380 • Level 4: Level 1-3 + Advanced functionalities for the analysis and combination of datasets.

381 Most of the identified repositories are at level 1. The few identified repositories at levels 2 and 3  
 382 have a broad scope and do not focus specifically on transport. None of the identified repositories  
 383 belong to level 4.

#### 384 4 Synthesis and outlook to further activities

385 In summary, the results of the workshop and the environment analysis identified two main drivers  
386 for digital platforms relevant to transport research: the regulatory frameworks at the EU and  
387 national level, and viable business models for the provision of mobility data and services.

388 The regulatory framework for the EU and its member states requests the establishment of digital  
389 platforms for data collected by public authorities and also private companies such as providers of  
390 sharing services. The ITS Directive requires EU Member States to establish NAPs and to make  
391 pre-defined data types openly available. In the future, the EU Regulation on the development of  
392 the trans-European transport network (TEN-T) approved in 2024 might also be relevant [21].  
393 The TEN-T regulation defines 431 cities in the EU as “urban nodes”, which are requested to  
394 submit “urban mobility data [...] in the fields of sustainability, safety and accessibility” to the  
395 European Commission for the first time by the end of 2027 [21]. The data and indicators to be  
396 submitted in this context have not yet been finally specified but it can be assumed that they will  
397 cover most of the boxes in Figure 1. Overall, it can be expected that in the coming years, an  
398 increasing number of digital platforms will be available to provide transport data from public  
399 authorities to meet the requirements of current and future regulations at EU, national and local  
400 levels.

401 Two main types of commercial platforms as viable business cases were identified:

- 402 1. Commercial platforms providing data (e.g., map data, FCD) come with promising oppor-  
403 tunities for research and planning practice, and also with challenges. Data collection and  
404 processing methods are often not transparent and there may be hidden biases in the data.  
405 Quality standards or benchmarks set by public authorities or other neutral institutions  
406 could help to ensure the trustworthiness and quality of such commercial data, to the benefit  
407 of providers and users.
- 408 2. Commercial platforms offering mobility services focus on their services. Mobility service  
409 providers set up the platforms to interact with their (potential) customers, but are less  
410 interested in providing data. Uber, on-demand services (e.g. Moia, <https://www.moia.io>) or  
411 carpooling services (e.g. scooters or bicycles) are examples of such commercial platforms.  
412 User-driven mobility services provided on these platforms can complement services  
413 provided (and funded) by public authorities for the benefit of society. At the same time,  
414 these platforms offer great opportunities for research into the impact of current services  
415 on travel behavior. Public regulation of these commercial platforms ensures that their  
416 services contribute to societal goals, and that data and services meet standards in terms of  
417 quality and transparency.

418 Most mobility services will fall within the scope of the ITS Directive. Service providers will  
419 therefore be required to make their data available (e.g., locations of bike/car sharing stations,  
420 availability of shared vehicles). Some municipalities are already imposing conditions on the  
421 provision of sharing services in their area and requiring operators to provide the municipality  
422 with data (e.g. on the availability of their services). Overall, the availability of data on mobility  
423 services is expected to increase in the coming years.

424 Looking back at Table 2, these two main drivers mainly support digital platforms provided by  
425 public authorities and private companies. This is also in line with the overview of stakeholders  
426 and their roles summarized in Figure 1. Public authorities, public transport operators, private  
427 companies providing on-demand mobility services, and industry (e.g., mobile phone companies)  
428 are all mandated (by the regulatory framework) or interested in operating digital platforms, while  
429 at the same time relying on digital platforms as a basis for ensuring access to destinations and to  
430 social participation for all population groups and/or for running successful businesses.

431 Such strong drivers do not exist for data collected in transport research, where data are mainly  
432 a means to an end. Data are collected, processed and analyzed to answer research questions,  
433 to complete research projects and doctoral theses. The motivation and resources to establish  
434 dedicated digital platforms for transport research data have so far been low. This is at odds with  
435 widely supported goals such as “open science” and “open data”. The workshop identified only  
436 one platform providing research data, the VAMOS platform operated by TU Dresden (see Table  
437 2). In the environment analysis, the [FID move repository](#) was the only identified stable platform  
438 with a focus on transport research data. Three main reasons have been identified for these deficits  
439 in the availability of digital platforms focused on transport research data:

- 440 • The transport research community is small and fragmented because of its interdisciplinary  
441 nature: researchers from different disciplines, with all their specific interests, vocabularies,  
442 and practices study transport systems as a domain.
- 443 • Data in transport research is very often sensitive in terms of personal characteristics and  
444 location information. Such data cannot and must not be made openly available without  
445 restrictions, and methods of data processing and user management must be in place to  
446 facilitate the provision of such data as openly as possible and as protected as necessary to  
447 comply with data protection legislation.
- 448 • The availability of data in transport research has only recently improved significantly  
449 thanks to digitalization, mobile devices, sensors, etc.

450 Looking back at Figure 1, different data types and sources in transport research are affected  
451 differently by the identified drivers and barriers. The three top boxes, which can be summarized as  
452 travel demand data (moving subjects and objects, movement of single subjects and objects, traffic  
453 flow), are the main focus of transport research and are therefore most affected by deficiencies in  
454 platforms providing these data. Regarding the data sources on the right side of Figure 1, data  
455 on travel demand are mainly collected through travel surveys, field observations (e.g. based on  
456 video recordings or other types of imagery) and, increasingly, through social media platforms  
457 and commercial platforms offering mobility services. For example, researchers can download  
458 location data from shared vehicles at a high frequency, generating new data about the users and  
459 usage of these services. All these data are highly sensitive in terms of privacy, both in terms  
460 of the characteristics of travelers and the places they visit. At the same time, the increased  
461 availability of these data offers promising opportunities. Thanks to the ITS Directive location  
462 data will be increasingly available from shared service providers. Travel survey data will become  
463 more detailed, thanks to smartphone apps, which are increasingly being used to collect these  
464 data. Image data from local field observations can increasingly be processed automatically (see  
465 e.g. emerging tools such as [OpenTrafficCam](#)) to generate traffic volumes, trajectory data and

466 conflicts for all user groups. The establishment of digital platforms for these data can facilitate  
467 their re-use of the data in research, for example for comparisons over time and between different  
468 locations. Transport research data from such platforms can also be used for comparison and  
469 benchmarking with similar data provided by private companies (e.g. mobile phone companies  
470 or car manufacturers) or for training Large Language Models (LLMs) focused on the transport  
471 domain. Overall, public funding, which is a main source of transport research, will be used more  
472 efficiently if platforms make the data collected and/or processed in the funded projects available to  
473 the public. The question is which institutions could take responsibility for creating such platforms  
474 focused on transport research data. Candidates for this role include research institutions with  
475 sufficient resources to establish and sustain such platforms (e.g., universities, DLR), the German  
476 research data management initiatives (Nationale Forschungsdateninfrastrukturen, [NFDI](#), and also  
477 the NAPs under the ITS Directive. The discussions at the workshop, as well as the results of the  
478 environment analysis, clearly show that investments in platforms providing sensitive transport  
479 research data are worthwhile and will pay off with significant benefits for research, planning  
480 practice, and private companies.

**481 5 Appendix****482 5.1 Workshop program****483 Day I (27/04/2023)**

484 1. Keynote - Dr. Charlotte Halpern: Data as a critical resource for governing sustainable  
485 urban mobility

486 2. Presentation Session A - Moderation: Charlotte Halpern

487 • Valeria Caiati: Does privacy concerns and trust influence users' intention to subscribe  
488 to MaaS platforms? Evidence from a hybrid choice model

489 • Miloš N. Mladenović: Adaptive governance of emerging mobility technologies: A  
490 framework for policy innovation and integration

491 • Paulo Jorge Teixeira Fernandes: Transforming urban mobility: An eco-routing  
492 service leveraging Internet-of-Things (IoT) technologies and Mobility as a Service

493 • Alejandro Tirachini: Ridesourcing and ridepooling in Latin America: research find-  
494 ings and policy developments

495 3. Keynote - Prof. Marc Steinberg: Automobile Lineages of the Platform Economy

496 4. Interactive Session

497 5. Presentation Session B - Moderation: Pascal Kerschke

498 • Christina Wolking: Overcoming challenges in implementing MaaS-Platforms

499 • Gernot Liedtke: MaaS in the context of transport sector development

500 • Meng Wang: Data-driven mobility research enabled by VAMOS lab

501 • Marc Widemann: Current regulatory framework and future developments on traffic  
502 and travel data in the EU

503 • Sam Hind: What now? An appraisal of 'post-pandemic' shocks to platform mobility  
504 in Tel Aviv

**505 Day II (28/04/2023)**

506 1. Keynotes

507 • Prof. Orit Halpern: Models and Cities: Re-imagining Smartness

508 • Prof. Travis Waller: Moving Into the Future: Infrastructure as Platform and Mobility  
509 as a Resource

510 2. Presentation Session C - Moderation: Travis Waller

511 • Konstantin Krauß: A framework for designing Mobility-as-a-Service business models

512 • Holger Drees: National Access Points for Mobility Data in Europe – Regulations,  
513 evolution and the example of the German NAP

- 514 • Sebastian Pretzsch: Mobility Data Spaces
- 515 • Erion Murati: Incentivizing the sharing of mobility data via a MaaS data governance
- 516 decision model
- 517 • Denis Reiter: Open geodata infrastructures and digital planning tools to support
- 518 mobility transitions
- 519 3. Interactive Session

520 5.2 Pinboards from interactive group work in the workshop

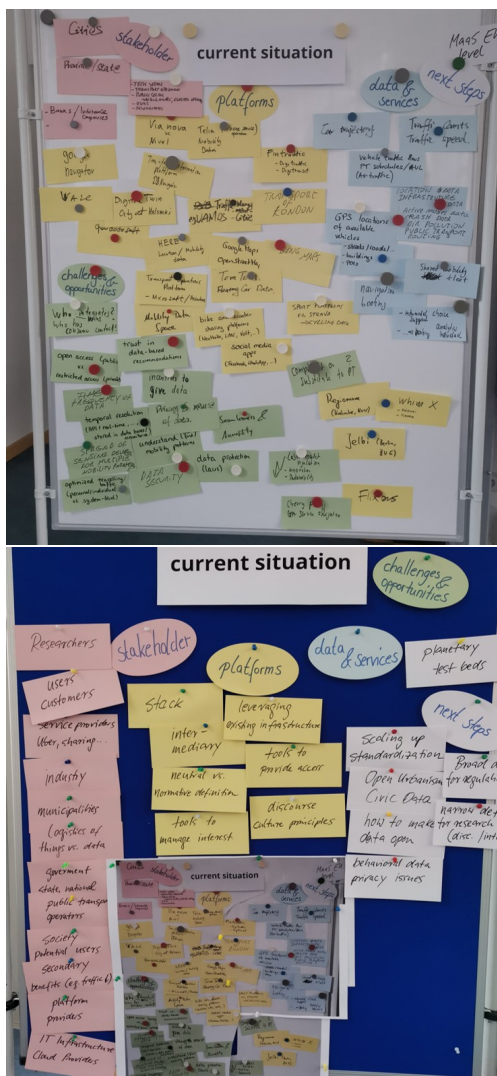

Figure 3: Pinboards current situation

Figure 4: Pinboards future perspectives

## 521 6 Acknowledgements

522 We thank all participants for their great contributions: Valeria Caiati (Eindhoven University  
523 of Technology), Holger Drees (BASt), Paulo Jorge Teixeira Fernandes (Universidade de Aveiro),  
524 Charlotte Halpern (Science Po, Centre for European Studies and Comparative Politics), Orit  
525 Halpern (TU Dresden), Sam Hind (Tel Aviv University), Georg Hirte (TU Dresden), Stefan  
526 Hubrich (TU Dresden), Konstantin Krauß (ISI Fraunhofer), Michael Krieg (TU Dresden), Gernot  
527 Liedtke (DLR), Miloš N. Mladenović (Aalto University), Erion Murati (University of Hamburg),  
528 Sebastian Pretzsch (ISI Fraunhofer), Denis Reiter (IÖR), Sujit Sikder (IÖR), Marc Steinberg  
529 (Concordia University), Alejandro Tirachini (University of Twente), Travis Waller (TU Dresden),  
530 Meng Wang (TU Dresden), Marc Widemann (BBG and Partners), Christina Wolking (TU Berlin).  
531 We thank Anett Ludwig and the local organization team from the “Friedrich List” Faculty of  
532 Transport and Traffic Sciences at TU Dresden for their great support. We also acknowledge  
533 support from NFDI4Ing and FID move.
